

Method for determining capacitor dielectric

Overview

Let's see how capacitance can be computed in systems with simple geometry. To calculate the capacitance, we first compute the electric field everywhere. Due to the cylindrical symmetry of the system, we choose our Gaussian surface to be a coaxial cylinder with length $A < L$ and radius r where $a < r < b$. Using Gauss's law, we have

The electric field is non-vanishing only in the region $a < r < b$. Using Gauss's law, we obtain

A capacitor can be charged by connecting the plates to the terminals of a battery, which are maintained at a potential difference ΔV called the terminal voltage. Figure 5.3.1 Charging a capacitor. The connection results in sharing the charges between the terminals and the plates. For example, the plate that is connected to the (positive) negative. eq with a total charge Q supplied by the battery. However, since Q is shared by the two capacitors, we must have $Q = Q_1 + Q_2 = C_1 \Delta V + C_2 \Delta V = (C_1 + C_2) \Delta V$.
