FLEXIBLE SETTING OF
MULTIPLE WORKING MODES

Overview

The case is the outermost covering of the battery. It is usually made of thin steel sheets. It acts as a holder and keeps the battery components and insulation away from the ambient. A plastic wrapper is placed over. Note: The positive terminal does not mean the cathode. But generally, both these terms are used interchangeably while discussing battery terminals. Actually, the cathode is present. Similar to the cathode, the anode also lies inside the battery, while the negative terminal lies outside. The negative terminal connects the anode to the circuit. In an alkaline battery, the anode has the capacity to release electrons. Alkaline batteries use zinc as the anode. This metal easily releases electrons. The zinc is mixed with potassium hydroxide solution. The cathode accepts the electrons released by the anode. Manganese dioxide is used in alkaline batteries as its cathode. Manganese oxide is mixed with graphite to increase its conductivity.
